Electronic Phenomena

Saturation current in photoconducting crystals. K. G. Ordzonikidze (Inst. Phys., Acad. Sci. Georgian S.S.R., Tbilisi). Soobshcheniya Akad. Nauk Gruzii S.S.R. 13, No. 1, 15-18(1952). A scheme is described by which the photocurrent is measured instantaneously while it is produced. Measurements were made in fields 0-40,000 v./cm. on transparent S crystals 1.2 mm. thick and on NaCl monocrystals colored by x-rays, KCl monocrystals colored by addn., and KCl monocrystals satd. with I₂. In the interval 2000-12000 v./cm. in S crystals the gradient of the photocurrent vs. the increase in field strength is retarded. Above 12000 v./cm. the photocurrent increases rapidly. For all 3 allochromatic crystals deviations from Ohm's law were also observed, above 30,000 v./cm. for NaCl, above 22,000 v./cm. for KCl with additive coloring, and above 24,000 v./cm. for KCl colored by I₂. Saturation can be explained by a limited value of the mean free path of photoelectrons. S.P.

Title : Investigation of Isotope Composition of Lithium

Orig Pub : Zh. eksperim. i teor. fiziki, 1955, 29, No 4, 479-485

Abstract : Investigation of the effects of separation of Li isotopes on evaporation of Li⁺ ions from the surface of W-powder and on ionization of molecular clusters of Li compounds by an electronic beam. In the former case, within the temperature interval 800 - 1200°, on evaporation of Li⁺ ions the ratio Li⁷ : Li⁶ increases with time, starting with the value 11.42. At higher temperatures Li⁷ : Li⁶ = 12.48 0.02 which practically coincides with the true value (12.47 0.02), derived by the integral method. By the described procedure was measured the isotope composition of Li in four minerals. In the second instance slight separation effects were detected.

TITLE: An automatic cascade apparatus for obtaining highly concentrated heavy nitrogen isotope

PERIODICAL: Atomnaya energiya, v. 10, no. 5, 1961, 487-492

TEXT: The growing use of N^{15} in different domains (for example, N^{15} nitrates in homogeneous reactors; N^{15} has a thermal neutron capture cross section of $2 \cdot 10^{-5} b$, whereas the value for natural nitrogen is $1.8 b$) makes it of interest to develop suitable methods for the preparation of this isotope. The principal difficulty lies in the smallness (0.365%) of N^{15} content in the natural nitrogen. Spindel and Taylor (Ref. 1: W. Spindel, T. Taylor. J. Chem. Phys., 23, 981 (1955); 24, 626 (1956); Trans. N. Y. Acad. Sci., 19, 3 (1956); T. Taylor, W. Spindel. Proceedings of the

An automatic cascade apparatus for...

International Symposium on Isotope Separation. Amsterdam, North - Holland Publishing Company, 1958, p. 158; L. Kauder, T. Taylor, W. Spindel. J. Chem. Phys., 31, 232 (1959)) have developed a cascade apparatus with two columns allowing N¹⁵ to be obtained with 99.8 % purity. On this basis the authors of the present paper have developed and constructed an automatic cascade apparatus that allows 99.8 % pure N¹⁵ to be obtained from natural nitrogen by the method of NO-HNO₃ exchange. The yield is about 0.5 g per day. The chemical exchange NO-HNO₃ is described in Ref. 1, and also in the introduction of the present paper. Fig. 2 shows the scheme of construction of the actual automatic apparatus; 3 and 6 (in Fig. 2) correspond to the first and the second column of the cascade. The HNO₃ is conveyed from the reservoir 1 to the first column via a regulating valve 4 and a flow meter 2. The enriched solution is taken through a regulating valve 5 and a second flow meter 2 to the upper part of the second column for further enrichment, the remaining part flowing through the sleeve type 7 into the reactor. In the reactor 10 HNO₃ reacts with SO₂. The oxide

Card 2/4

An automatic cascade apparatus for...

22876
S:059/61/C10.005/004.015
B1C2,B2+C

mixture produced is led into the column 3 where it reacts with nitric acid with isotope exchange. The HNO₃ from column 6 enters the reactor 9 (which is analogous to the reactor 10). The nitric oxide from the reactors is brought back to the column 6 and reaches finally the lower part of the first column. The NO free of N¹⁵ is discharged from the cascade; the H₂SO₄ formed in the reactors is led off to the reservoir. The HNO₃ enriched in N¹⁵ is led away from the lower part of the second column through an electromagnetic dropper 8. Columns, valves, and connecting pieces are made of nonrusting steel of the type 1X19H9T (1Kh19N9T). The packing material is teflon. The reactors consist of quartz. The automatic regulation is related to the stabilization of the acid and water flows in the large and small reactor, to the stabilization of the quantity of the discharged product (acid), and the regulation of the gas addition. The regulating system consists of the automatic stabilizers, a signal block controlling the automatic regulators and stabilizers, and a feeding block. The whole regulating system is free from contacts in its working and must give an accurate and reliable performance over a period of

Card 3,4

An automatic cascade apparatus for...

operation. The enriched samples (N_2 and NO) were subjected to a mass spectroscopic investigation which allowed the isotopic composition to be determined to an accuracy of $\pm 0.02\%$. Depending on the amount of nitrogen taken the concentrations are given by:

Nitrogen taken, g/day	N^{15} concentration, %
0.55	39.8
0.69	64
0.84	50

TITLE: Origin and characteristics of delayed reactions in dogs

SOURCE: AN GruzSSR. Institut fiziologii. Trudy, v. 14, 1965. Sovremennyye problemy deyatel'nosti i stroyeniya tsentral'noy nervnoy sistemy (Present problems of the activity and structure of the central nervous system), 23-38

TOPIC TAGS: delayed reaction, delayed response, visual stimulus, conditioned response, delayed conditioned response

ABSTRACT: The ability of dogs to produce delayed responses to various kinds of stimulus (ocular, auditory, and vestibular) was studied. Delayed responses to visual stimuli are performed by dogs with different delay maximums. In quiet, immobile dogs the maximum delay of alimentary response to a visual stimulus may be 10--15 min. In active, easily excited dogs the delay maximum does not exceed 3 min. The duration of delayed reaction greatly depends on the repetition of the experiment, i.e. on training. Maximum delay is achieved by alternating short delays with longer ones until the maximum is reached. The maximum delay is reached much faster and far more successfully in quiet, immobile dogs than in easily excited dogs. However, the abil-

Card 1/2

L 22215-66
ACC NR: AT5024225

O

ity of the animals to produce delayed responses does not exclusively depend on training. Animals may produce delayed responses at the first trial, some minutes after they have seen the food or heard the signal. The delay of responses to conditioned stimuli (bell, tone) was somewhat shorter (8-12 min). The maximum delay of responses to conditioned natural signals (noise of food basin) was significantly shorter (3-5 min). In experiments with visual stimuli and conditioned food signals, unusual stimulation during the delay period, even feeding or removal of the animal from the cage, did not disrupt the delayed response. Maximum delay of response to conditioned sound stimuli is somewhat more difficult to achieve than with visual stimuli. The animals were also able to produce delayed responses to vestibular stimulation. The maximum delay for these stimuli is 3-4 min. These findings are theoretically analyzed in the light of psychoneural regulation of the behaviour of higher vertebrates. It is concluded that delayed reactions are governed mainly by the laws of the psychoneural activity producing images of the external world, and not by the laws of conditioned activity.

TITLE: The effect of elemental sulfur on the chemical stability of distilled fuels

SOURCE: Neftepererabotka i neftekhimiya, no. 2, 1964, 14-17

TOPIC TAGS: sulfurous kerosene, kerosene discoloration, fuel stability, fuel sulfur content, gasoline corrosion

ABSTRACT: This is a review, mostly of Soviet sources, concerning the detrimental influence of the elemental sulfur formed in fuels containing sulfur compounds. Elemental S present in hydrogenated products reacts with hydrocarbons and forms unstable resins, some of which are distilled with kerosene and affect its color in storage. The presence of 50-200 mg elemental sulfur per liter in the hydrogenated product makes the color unstable and the fuel useless as illuminating oil. During fractionation of sulfur-containing crude there is a definite dependence of kerosene stability on distillation temperature. This fact should also be taken into consideration when judging the stability of aviation kerosenes. Elemental sulfur in gasoline makes it corrosive. Elemental sulfur is formed through the oxidation of hydrogen sulfide during fractionation or secondary processing of oils. Orig. art. has: 4 tables.

Destructive hydrogenation of coals. I. B. Rapoport,
D. B. Oreshkin and V. N. Chubarovskii. Khim. i Tekhnol.
Topliss 5, 33-91 (1934).—Powd. samples from Bar-
ras (a) and Moscow coal (b) were hydrogenated. The
former contained: H₂O (volatile) 2.16, ash (dry) 29.48, total
S (dry) 2.61; on the combustible mass: C 79.43, H 9.00,
volatile matter 74.66%, heating value (combined mass)
(1044 cal); semi-coke 34.8, tar on the combustible mass
52.2, H₂O of decomps. 3.5 and gas and losses 25.3%
The Moscow coal analyzed: H₂O 7.00, ash 33.74, total S
1.78, C 67.72, H 5.21 and volatile matter 48.07%
Carbonizing (a) at 410-460° during 90-260 min. and 0-30
atm. yielded: residual coal 49.0-60.3, distillate 9.7-29.0
and H₂O 4.5-6.2%; the gas gasoline amounted to 1.7%
gas and losses 15.8-24.9%. The distillate yielded: 7.2-
10.1% gasoline (on coal) of 0.703-0.774 sp. gr. Hydro-
genation of the coal at 340-450°, for 30-240 min., 110-220
atm. pressure in the presence or absence of catalysts, such
as 10% NiO or 0.5-5.0% NH₄ molybdate, yielded: gas
gasoline 0.7-3.5, residue 28.5-70.8 (contg. coal 31.0-37.5
and oil 0.9-39.1%), total yield of liquid products 31.9
49.0 and gas and losses 13.5-43.7%. The hydrogenation
of (b) with the above catalyst at 380-480°, other condi-
tions remaining the same, yielded 0% of gasoline after
2 recyclings, and the 4th recycling yielded another 6.7%
The total yield of liquid products amounted to 12-14%
and 3.8% more oil was extd. with C₆H₆. Hydrogenation
of the sample treated with HF in the presence of
NH₄ molybdate catalyst yielded: distillate 46, H₂O 2.3,
coal 31.2 and losses 27.4%. The liquid fraction contained
gasoline 12.4-34.8, kerosene 21.7-47.9 and residue 16.1-
49.6%.

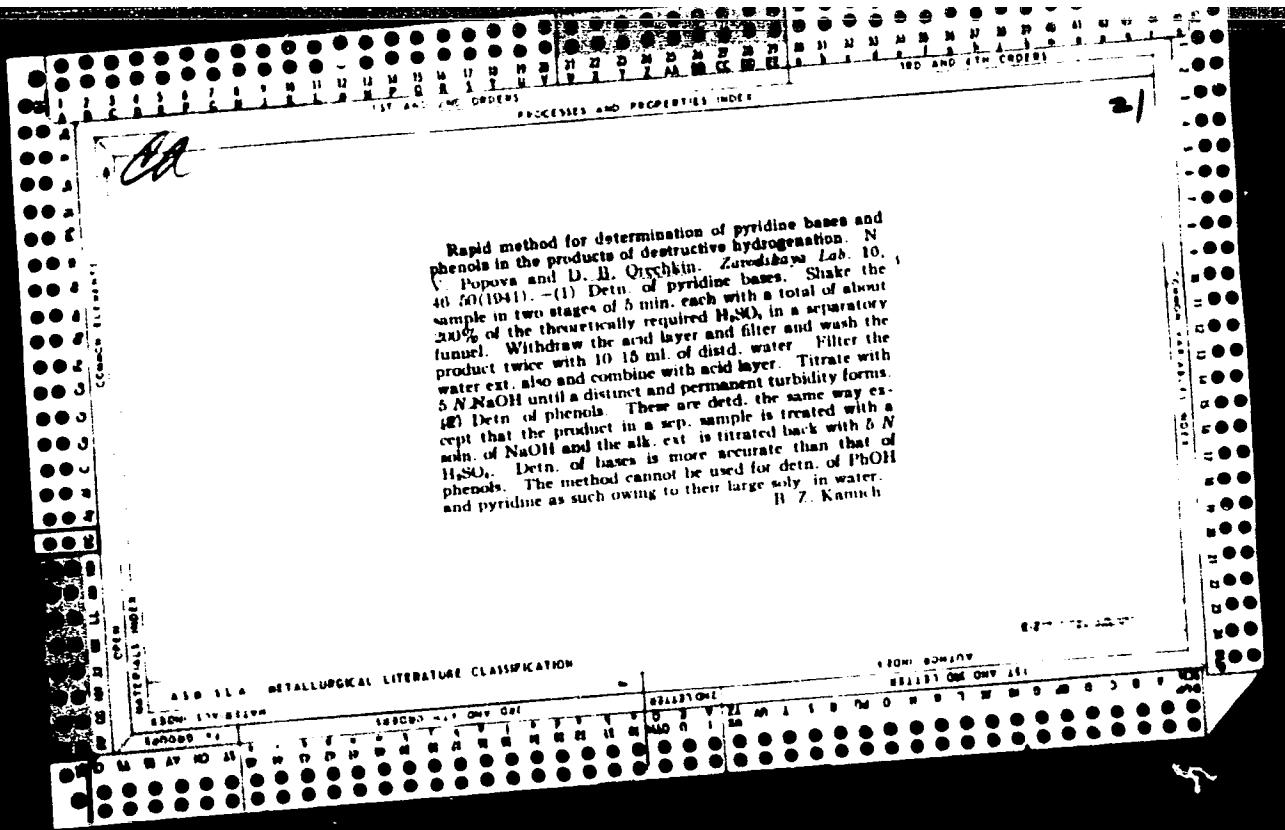

A. A. Boehtlingk

Low-temperature carbonization of coals from the Plot
mineral district. A. N. Bashkurov and I. B. (Vrechbin
Kham. Turdye Topiro 5, 621-511034). - The PLOTNIKOV-
skil coals are mined near Kuchengino in Siberia. On low-
temp. carbonization a powdery coke is obtained in addn.
to 12.20-13.24% tars (and other products) contg. phenols
25.70-27.00, carboxylic acids 0.30-0.25 and bases 2.00-
2.00%. The benzine, which is high in phenols, carboxylic
acids and bases, yields after treatment with H₂SO₄ and
NaOH (losses 8%) a product of d. 0.777, I no. 121, S
0.24% and unsat'd. aromatic compds. 62%. A. A. B.

Determination of "mechanical admirabiles" in products used in the hydrogenation of coal. D. B. Onuchkin and N. V. Popova. Zemstvoskoye Lab. 9, T234-6 (1940). - The method is based on the rapid dist. of asphaltene by centrifuging. Place about 6 g. of the product in a weighed tube 140 mm. high and 30 mm. in diam. having a spout and a special arrangement for retaining the mech. adm. Heat on a water bath until the sample melts, add 50 ml. of hot benzene, mix carefully with a glass rod and then centrifuge for 10 min. Decant the benzene carefully and completely. Wash and centrifuge 3-4 times, then place on a water bath at 60° to evap. benzene, dry for 1 hr. at 105°, cool to room temp. and weigh. B. Z. Kamka

Rapid method for determination of pyridine bases and phenols in the products of destructive hydrogenation. N. V. Popova and D. B. Ossipkin. Zavodskaya Lab. 10, 40, 50(1941). -(1) Detn. of pyridine bases. Shake the sample in two stages of 5 min. each with a total of about 200% of the theoretically required H_2SO_4 in a separatory funnel. Withdraw the acid layer and filter and wash the product twice with 10-15 ml. of distd. water. Filter the water ext. also and combine with acid layer. Titrate with 5 N NaOH until a distinct and permanent turbidity forms. (2) Detn. of phenols. These are detd. the same way except that the product in a sep. sample is treated with a min. of NaOH and the alk. ext. is titrated back with 5 N H_2SO_4 . Detn. of bases is more accurate than that of phenols. The method cannot be used for detn. of PhOH and pyridine as such owing to their large solv. in water.

Chem., 1955, (3), 105-126; abstr. in Chem. Abstr., 1956, Vol. 50, No. 5).
The transformation of coal matter to the liquid phase is based on reducing
depolymerization processes, i.e., the cracking of the macromolecule of humic
matter by breaking the weak C-O bonds which join the carbon complexes which
are the structural elements of coal matter. The primary stages of the thermal
decomposition of coal can be represented by two interrelated processes:
(1) reducing depolymerization which results in the isolation of the coal
complexes, a decrease in the average molecule weight of the coal matter, and
the transformation into liquid or low-melting material, and (2) a reverse
process which consists of removing oxygen in the form of water with a
simultaneous condensation of the carbon complexes. This results in an
increase in the carbon skeleton of the molecule of coal matter and a loss in
its fusibility. The predominance of either of these processes depends upon
the hydrogen content of the coal and upon the medium in which the thermal
decomposition is carried out. The presence of hydrogen under pressure or of
hydrogen will direct the decomposition as a source of hydrogen will direct the decomposition of the coal or

TITLE: Refining of Petrolatum by Hydrogenation Under High Pressure. (Oblagorazhivaniye petrolatuma putem gidrirovaniya pod vysokim davleniyem).

PERIODICAL: Khimiya i Tekhnologiya Topliv i Masel, Nr.5. 1959. pp. 47 - 51. (USSR).

ABSTRACT: A sample of petrolatum obtained from the Novo Ufimskiy Petroleum Refinery was hydrogenated. Characteristics of the sample are given in Table 1. During investigations in an autoclave, it was found possible to separate almost all the tar admixtures from the petrolatum. Experiments were also carried out on a continuous pilot plant with 100 ml catalyst capacity. A final experiment was carried out in a 12 l experimental plant during hydrogenation on a pilot plant scale; 2 industrial catalysts were used: pure tungsten sulphide (1) tungsten sulphide plus nickel sulphide, precipitated on active aluminium oxide (2). In both cases the pressure of hydrogen was maintained at 300 atms. When the first catalyst was used, refining of the petrolatum occurred at 320°C and a volume rate of 1 hr⁻¹. The sulphur content was reduced to 0.1% and a comparatively small cleavage of the starting

Card 1/3

sov/65-58-9/14
Refining of Petrolatum by Hydrogenation Under High Pressure.

material occurred. Similar results were obtained when the second catalyst was used at 360°C, but in this case a slightly higher degree of cleavage could be observed. In later experiments the influence of increased temperatures was investigated. Fig.2: a photograph of the initial and the hydrogenated petrolatum sample. The catalyst, during experiments on an industrial scale, was used for 500 hours when hydrogenating the petroleum fraction boiling between 280 and 350°C. The activity of the catalyst was found to be practically unchanged. The hydrogenated petrolatum sample, prepared in a 10 litre apparatus, was tested in GrozNII (Results - Table 3). The first two fractions, representing about 10% which had crystalline properties and structure, showed the characteristics of solid paraffins. Table 4 compares the properties of hydro-petrolatum and white vaseline. The petrolatum sample was tested in the Central Research Institute of the Tanning Industry (Tsentral'nyy nauchno-issledovatel'skiy institut khimicheskoy promstilennosti) to evaluate its suitability as a lubricant substitute in the leather industry. Hydrogenated petrolatum is also of great interest as a raw

Premise. This book is intended for chemical engineers and economic planners concerned with the industrial development of Eastern Siberia.

Content. This volume is one of a series of 12 containing the Transactions of the Conference on the Development of the Production Forces in Eastern Siberia. The conference was held in August 1953. The volume contains summaries of 20 reports presented at the meetings of the Chemical Section of the Conference, brief summaries of permanent discussions, and the work of resolutions taken by the Chemical Section. The reports deal with the possibilities of developing chemical industries in Eastern Siberia, organic or synthetic artificial fibers, explosives, plastics, applicable detergents, special rubbers, mineral fertilizers, sulfuric acid, dyes, colorants, etc. ■ personalities are mentioned. There are no references.

TITLE: The Hydrogenation of Methyl Ethers of C₇-C₉ Acids Over a Zinc-Chromium Catalyst

PERIODICAL: Zhurnal prikladnoy khimii, 1960, Vol 33, Nr 4, pp 980 - 983

TEXT: In the production of higher fatty acids from paraffins C₇-C₉ acids are obtained which are not widely used. Hydrogenation of these acids produces the corresponding alcohols which are more valuable. For hydrogenation copper-chromium catalysts with additions of oxides of alkali earth metals are used. In the article a zinc-chromium catalyst is investigated which is considerably stabler than a copper-chromium catalyst. The optimum conditions for the hydrogenation of the methyl ethers of C₇-C₉ acids over a zinc chromium catalyst are a pressure of 300 atm, a temperature of 300°C, a volume flow rate of H relative to raw material of 0.4 - 1.2 and a hydrogen consumption of 1,900 l per 1 liter of raw material and hour. At 300°C the catalyst shows a good

TITLE: Some Properties of Tungsten Sulphide Catalysts

PERIODICAL: Khimiya i tekhnologiya topliv i masel, 1961, No. 1
pp. 25-28

TEXT. A method has been devised for the rapid prediction of the stability of tungsten sulphide catalysts, and some reasons for its deactivation discovered. The catalyst is normally supplied in the form of pellets 10 x 10 mm, with a breaking stress of 250-300 kg/cm². The BET (BET) surface area is 60-70 m²/g, and the mean pore radius 17 Å. The prediction method consists in soaking the pellets in an aromatic solvent, preferably orthoxylene, for 10 minutes. During that time any mechanically unstable pellets will break up either into fragments, or into powder, under the action of adsorption of liquid and release of gas bubbles. The percentage of pellets left as whole, as fragments, and as powder, after that time is then counted. There is a very strong correlation between the resistance of the pellets to this treatment, and the useful

Card 1/2

S/065/61/000/001/005/008
E030/E212

Some Properties of Tungsten Sulphide Catalysts

catalyst life, as determined both under pilot plant and industrial operation. For instance, two types of catalyst pellet were left 100% and 4.6% whole after the test treatment, and in practice they lasted 110 and 10 days, respectively, after which they were 82% and 53% whole. Correlation between mechanical stability, as determined above, and chemical stability and activity exists. The reason is the deposition of carbon on the catalyst. By slicing pellets with a microtome, and examining the carbon content as a function of distance from the pellet surface, a steep maximum (around 5%) is found about 0.05 to 0.1 mm from the surface, tailing off to a constant level (about half the maximum) within. This is due to diffusion of feed and hydrogen, subsequent cracking and coke formation within, and sealing of the interior to further diffusion. Thus, the pore volume rapidly drops, and the reactor pressure drop increases, and the surface area falls to 10-15 m²/g. It is therefore essential to maintain a high partial pressure of hydrogen to inhibit coke formation. There are 1 figure, 2 tables and 4 references: 2 Soviet and 2 non-Soviet.

TITLE: Hydrofining the kerosene fraction

SOURCE: Neftepererabotka i neftekhimiya, no. 4, 1965, 14-16

TOPIC TAGS: hydrofining, kerosene, hydrogenation, dearomatization sulfide, catalyst / 3076 catalyst, 5058 catalyst

ABSTRACT: An important solvent for acetylene production is the highly dearomatized petroleum fraction from naphthalene-paraffin hydrocarbons boiled off at 200-250°C. This solvent must contain no more than 0.3% aromatic compounds. The authors sought to find the optimal conditions for obtaining this solvent by hydrogenation with industrial sulfide catalysts: 5058 (tungsten sulfide) and 3076 (mixture of nickel and tungsten sulfides). Tests were made at high pressure with the catalyst ground to 3-4 mm. The duration of each experiment was about 48 hours. Hydrogenation with 3076 was carried out at 300 atm and at temperatures of 300 and 350°C. Good results were obtained at 350°C, the product having only 0.2% aromatic hydrocarbons at low delivery rates and still only 0.3% at higher rates. The yield of solvent in this process amounted to 68.2-78.5% of the initial

Card 1/2

L 53599-65

ACCESSION NR: AP5010980

raw material. Hydrogenation at 300C was unsatisfactory (yielding too much aromatic material). Hydrogenation of 5058 was also carried out at 300 atm, but at temperatures of 300, 320, 340, and 360C. Again hydrogenation at 300C was unsatisfactory. At 320C the aromatic content was less, but not sufficiently less. At 340C results were satisfactory, and were even better (lower aromatic content) at 360C. Results were thus satisfactory with either catalyst, but the yield was 7-10% better with 3076.
